Biological Studies of high caloric foods supplemented with some probiotic bacteria

Sherief S.; Nehad R. EL-Tahan and Doaa E. A.
Nutrition and Food Science Dep., Faculty of Home Economics, Menofia University, Egypt

Abstract: Effect of different percent of high caloric food components (Lupine, chickpea and soyprotien) with probiotics bacteria on some biological and histological parameters of albino rats were studied. Thirty adult male rats were distributed into six groups, the first one was kept as control group, while the other five groups were fed on high caloric diet and supplemented with some probiotic bacteria for 6 weeks. Results showed that body weight gain markedly was higher especially in the mixture of group (6) 1:1:1:1%) compared to control group and group which fed without probiotics. Also, this mixture with high probiotics lowered concentrations of total cholesterol, triglycerides, LDL-c, VLDL-c and decreased activity of AST and ALT enzymes to normal range. Furthermore, all mixture caused significant increase in HDL-c and total immunoglobulin production (IgG, IgM, IgE, IgA) were higher than the mixture (1% lupine, chickpea, soyprotien) without probiotics.

Histopathological examination showed amelioration of histopathological lesions seen in liver of rats received the mixture of seeds at different levels with probiotics. So, it could be recommended that intake of the mixture of lupine, chickpea, soyprotien and probiotics especially at 1:1:1:1 respectively may be useful for high caloric foods.

Key words: Male rats, lupine, chickpea, soyprotien, probiotics, histopathological structure.

الملخص العربي

تم في هذا البحث دراسة الأغذية عالية الطاقة (الترمس والحمض وبروتين الصويا) المدعمة
بعض أنواع من البروبيوتوك على بعض العوامل البيولوجية والتنسيجية في ذكور الفئران الطبيعيه الالبينو.

وتم استخدام ثلاثين من الفئران البالغة تم تقسيمها إلى ستة مجموعات، المجموعة الأولى مجموعة
ضابطة في حين أعطت 5 مجموعات الأخرى يوميا خليط من (الترمس والحمض وبروتين الصويا
بنسبة 1:1:1) ونسبة من البروبيوتوك بنسبة 5%. 1% لمدة 3 أسابيع، وأظهرت النتائج أن الزيادة في
وزن الجسم كان أكثر بشكل ملحوظ خاصة في خليط من (الترمس والحمض وبروتين الصويا و
البروبيوتوك المضافة) بنسبة 1:1:10 مقارنة مع المجموعة الضابطة السالبة و أيضا حديث خفض
ALT و انخفاض نشاط انزيمات VLDL، LDL، و تركيزات الكوليسترول الكلي والدهون الثلاثيه. ووعلاوة على ذلك، حدثت زيادة كبيرة في تركيز HDL و كذلك زيادة واضحة في دلالات المناعة خاصة
مع المجموعات التي تغذى على البروبيوتوك.

وأظهر فحص الأنسجة تخسيس الخلايا النسجية في كبد الفئران التي تغذى على خليط من
الحبوب والبروبيوتوك على مختلف المستويات. وتوصي هذه الدراسة أن تناول خليط الترمس والحمض
وبروتين الصويا والبروبيوتوك وخصوصا بنسبة 1:1:1 قد يكون من فعّلاء هاتين تحسين الوضع
وزيادة الوزن بصورة صحية.

الكلمات الرئيسية: الفئران الذكور من نوع الالبينو- الترمس- الحمص- بروتين الصويا-
البروبيوتوك(لاكتوباسيلس والبيفيديكتريا) والتركيب التشريحي.
INTRODUCTION

A probiotic is defined classically as a viable microbial dietary supplement that beneficially affects the host through its effects in the intestinal tract. This definition, however, was initially intended for use with animal feed products. For human nutrition, the following definition has been proposed: A live microbial food ingredient that is beneficial to health (Salminen et al., 1998).

A prebiotic is defined as a non digestible food ingredient that beneficially affects the host by selectively stimulating the growth and/or activity of one or a limited number of bacteria in the colon. Modification by prebiotic of the composition of the colonic microflora leads to the predominance of a few of the potentially health-promoting bacteria, especially, but not exclusively, lactobacilli and bifidobacteria (Gibson and Roberfroid, 1995).

found that food can be said to be functional if it contains a component (which may or may not be a nutrient) that affects one or a limited number of functions in the body in a targeted way so as to have positive effects on health or if it has a physiologic or psychologic effect beyond the traditional nutritional effect (Clydesdale, 1997).

Among the most promising targets for functional foods are the gastrointestinal functions, including those that control transit time, bowel habits, and mucosal motility as well as those that modulate epithelial cell proliferation. Promising targets are also gastrointestinal functions that are associated with a balanced colonic microflora, that are associated with control of nutrient bioavailability (ions in particular), that modify gastrointestinal immune activity, or that are mediated by the endocrine activity of the gastrointestinal system. Finally, some systemic functions such as lipid homeostasis that are indirectly influenced by nutrient digestion or fermentation as lactobacilli and bifidobacteria represent promising targets.

Legumes have played an important role in the traditional diets of many regions throughout the world. It is difficult to think of the cuisines of Asia, India, South America, the Middle East, and Mexico without picturing soybeans, lentils, black beans, chickpeas, and pinto beans, respectively. In contrast, in many Western countries beans play a less significant dietary role. In fact, bean intake has actually declined during the past century in many European countries (Roberfroid, 2000).

The lupin is devoid of starch, which is very unusual for a species of edible bean. Lupins have a thick seed coat (25%) which consists mainly of cellulose (insoluble fibre-bran) and its removal is the first step in lupin processing. The kernel (split) of lupin is rich in protein (40%), fibre (40%) and moderate in fat (8%) made up largely of unsaturated fatty acids. Intensive plant breeding programs have ensured that modern lupin varieties have relatively low levels of the alkaloids found in their ancestral genotypes. Lupins also contain moderate amounts of carotenoids; beta carotene, lutein, zeaxanthin and tocopherols (Vitamin E). Australian sweet lupin features a higher calcium and phosphate content than cereals with trace element content varying in line with the mineral content of the soil in which the lupin is grown. Lupin oils have high
antioxidant capacities due in part to the presence of tocopherol (Vitamin E – the total vitamin E content is about 2.3-4.6 mg/kg of oil) (Williamson et al., 1994).

Chickpea (Cicerarietinum L.) is one of the world’s most important grain legumes because it is a valuable source of protein, minerals and vitamins, and plays a very important role in human diets in many areas of the world. Chickpea is an excellent source of protein, carbohydrates, and fiber, and provide many essential vitamins and minerals. Their highly nutritional properties have been associated with many beneficial health-promoting properties, such as managing high cholesterol and type-2 diabetes and in the prevention of various forms of cancer. The main antioxidant compounds in legumes are vitamins C and E, phenolic compounds and reduced glutathione (GSH). Different studies have shown that they have a protective antioxidant effect on cancer and cardiovascular diseases (Mallilinet et al., 2008 and Murty et al., 2010).

Soybean protein is a "complete protein" since it provides all of the essential amino acids for human nutrition. Soybean protein is essentially identical to that of other legume pulses and is one of the least expensive sources of dietary protein. For this reason, soy is important to many vegetarians and vegans. Soy flour contains 50% protein. The digestibility of some soy food are as follows: Steamed soybeans 65.3%, tofu 92.7%, soy milk 92.6%, and soy protein isolate 93–97%. Consumption of soy protein in place of animal protein has been found to reduce serum concentrations of total cholesterol, low-density lipoproteins (LDLs) and triglycerides. One theory proposes that cholesterol absorption is impaired or altered. Another theory postulates that phytoestrogens (plant compounds that have hormone-like effects; isoflavones are the phytoestrogens found in soy products) bind to estrogen receptors and produce similar effects including lowering LDLs and increasing high-density lipoproteins, vasomotor tone changes, and arterial wall function (Hasler, 2002).

So, this research aimed to study the effect of these legumes mixture with probiotic on some biological and histopathological parameters.

MATERIALS AND METHODS

Lupine, chickpea and soy protein were obtained from the local market of seeds and probiotics ((lactobacilliscasei, pifidobacterium acidophilus ) were obtained from (Lacteol fort) from Tenth Raadan for pharmaceutical Industries and Diagnostic Reagents (amedia) 6th of October City A.R.E and scientifically identified at Horticultural Research Institute, Agriculture Research Center, Egypt. All chemicals and diagnostic kits were purchased from El-Gomhoria Co., Cairo, Egypt.

Experimental animals: This study was carried out on thirty adult male Sprague Dawley albino rats weighing 160±5 g body weight. The rats were obtained from Laboratory Animal Colony, Helwan, Egypt. Before their use in the experiment, the rats were kept for one week for acclimatization to the laboratory conditions. They were fed on basal diet and provided with water and food ad libitum.
The basal diet consisted of casein (10%), cellulose (5%) salt mixture (4%), vitamin mixture (1%), corn oil (10%) and corn starch (70%) according to Reeves et al. (1993).

Experimental procedure: Rats were divided into six groups consisting of five rats each. The first group was fed on the basal diet and kept as a control group, while the other groups were fed on lupine chickpea and soy protein with probiotics for 6 weeks as the following: Group (2) mixture of lupine, chickpea with as(1:1 0.5%) probiotics. Group (3) mixture lupine, soy protein and probiotics as(1:1:0.5%). Group (4) lupine, chickpea and soy protein without probiotics as(1:1:1 %). Group (5) mixture lupine, chickpea, soy protein and probiotics as(1:1:1:0.5%). Group (6) 1% mixture lupine, chickpea, soy protein and probiotics as(1:1:1:1 %).

During the experiment period, the feed intake and body weight were recorded weekly. Body Weight Gain (BWG) and Feed Efficiency Ratio (FER) were calculated at the end of the experimental period according to the following equations:

\[
\text{BWG (g)} = \text{final weight (g)} - \text{initial weight (g)}
\]

\[
\text{FER} = \frac{\text{weight gain (g)}}{\text{feed intake (g)}}
\]

Collection of blood samples and organs: At the end of the experimental period, rats were sacrificed following a 12 h fast. The rats were lightly anaesthetized by ether and about 7 ml of blood was withdrawn from the hepatic portal vein into dry centrifuge plastic tubes. Blood portal vein into dry centrifuge plastic tubes. Blood separate the serum samples which were kept in tubes at -20 °C till biochemical analysis (Jeyakumar et al., 2006).

Biochemical analysis: Serum total cholesterol was calorimetrically determined according to Allain et al. (1974) and triglyceride was determined calorimetrically according to High Density Lipoprotein cholesterol (HDL-c) was determined calorimetrically according to Richmond (1973). Low Density Lipoprotein cholesterol (LDL-c) and Very Low Density Lipoprotein cholesterol (VLDL-c) were calculated mathematically according to Friedewald et al. (1972).

\[
\text{LDL-c} = \text{TC} - \left[\text{HDL-c} + \frac{\text{TG}}{5}\right]
\]

\[
\text{VLDL-c} = \frac{\text{Triglycerides}}{5}
\]

The activity of Aspartate Aminotransferase (AST) and Alanine Aminotransferases (ALT) enzymes were assigned by the method of total immunoglobulin (IgG, IgM, IgE and IgA) determined by Radioimmunoassay as described by the method of Patrono and Peskar (1987).

Histopathological study: Livers of the scarified rats were dissected, removed, washed with normal saline and put in 10% formalin solution. The fixed specimens were then trimmed, washed and dehydrated in ascending grades of alcohol. The tissue specimens were cleared in xylene, embedded in paraffin, sectioned at 4-6 microns thickness, stained with Hematoxylen and Eosin (H and E) and then studied under an electronic microscope according to (Carleton, 1979).

Statistical analysis: Results are expressed as mean values with their standard deviation of the mean. Statistical differences between groups were
RESULTS AND DISCUSSION

1-Effect of mixture of lupine, chickpea, soyprotien and probiotic on feed intake (FI), body weight gain (BWG) and feed efficiency ratio (FER) in normal rats.

Data in table (1) showed that feeding on mixture in group (6) which fed on 1% mixture lupine, chickpea, soyprotien and %1 probiotics led to increase the feed intake which was near to the normal group. The feed intake of the other tested groups were lower than the group (6) and normal group. There is no significant changes between group 2, 3 and 5. The group (4) which fed on %1 lupine, %1 chickpea and %1 soyprotien without probiotics was the lowest feed intake. For body weight gain, there is no significant differences between group (2) and group(5) and also between groups (1) and (6). There were significant differences between control group and the tested groups except group 6. In case of feed efficiency ratio, the sixth group was the best group and there is no significant change between this group and the control group. The lowest group for FER was the fourth group. This results were matched with Salminen et al. (1998) that probiotic improve the feed intake and body weight of rats. Probiotic as functional foods enhanced the gastrointestinal functions, including those that control transit time, bowel habits, and mucosal motility as well as those that modulate epithelial cell proliferation (Clydesdale, 1997).

Table (1): Effect of mixture of lupine, chickpea, soyprotien and probiotic on feed intake (FI), body weight gain (BWG) and feed efficiency ratio (FER) in normal rats.

2-Effect of mixture of lupine, chickpea ,soyprotien and probiotic on serum lipids

Administration of the mixture of lupine, chickpea, soyprotien, and probiotics at different levels caused significant decreases in serum of total cholesterol, triglycerides, LDL-c and VLDL-c compared to control group (Table...
2. Serum HDL-c levels increased but not significantly by the administration of the mixture of lupine, chickpea, soy protein and probiotics. Rats that were given mixture of lupine, chickpea, soy protein, and probiotic bacteria at the levels 1:1:1:1 (group 6) showed significantly higher levels of HDL-c compared to control group. The value of group four which fed on the mixture of seeds without probiotics were lower for HDL-c than control group while it was higher for the other lipid parameters than control group and the group (6). The obtained results in the same line of (Hasler; 2002). who found that soy protein can decrease LDL-c, total cholesterol and increase the level of HDL-c. Also, Clydesdale (1997) reported that probiotics reduce the absorption of lipids from diet.

3- Effect of mixture of lupine, chickpea, soy protein, and probiotic on liver function enzymes in normal rats.

From data presented in table (3) the administration of mixture of lupine, chickpea, soy protein, and probiotics group as 1:1:1:1 significantly reduced AST and didn't effect on ALT level when compared with the other treatment groups. There is no significant differences between group 1 and 5 also between group 2 with 3. On the other hand, there were no significant between group 1, 5 and 6. While, there significant changes between group 4 and the other groups. From the above results, It could be noticed that crude fiber in legumes is a group of indigestible carbohydrates can improve the function of the alimentary tract and also lower blood glucose, cholesterol levels and liver functions (Roberfroid, 2000).

4- Effect of mixture of lupine, chickpea, soyprotieng and probiotic on immunological productions.

From table (4), it could be observed that administration of the tested legumes and probiotics at (1:1:1:1) it is Effect to rats activity (group 6). The mixture of seeds (lupine, chickpea, soyprotieng and probiotics bacteria induced significant increased in serum levels of immunological profile compared to control group. All other tested mixture of legumes caused non significant changes in serum level of immunological productions. The main antioxidant compounds in legumes are vitamins C and E, phenolic compounds. So, different studies have shown from where that they have a protective antioxidant effect on immunity status, cancer and cardiovascular diseases (Mallilinet al., 2008 and Murty et al., 2010).

DISCUSSION

Several studies have showed that each of soy protien have long been recognized as an excellent source of high-quality protein. The soyprotien also contains a wide variety of chemical compounds that have potent bioactivity. Among these compounds are the isoflavones and the saponins. The goal of this research was to quantify isoflavone and saponin concentrations in elite soybean cultivars grown in different environments and to identify a naturally occurring high and low variety that could be used in animal studies of colon cancer they reportedsignificant environment genotype interactions for the cultivars and selected 2 that provided the range of concentration for isoflavones and saponins. These were grown in an adequate quantity for animal studies, which are ongoing. They explored the influence of isoflavones and saponins on human colon tumor cells in culture, Caco-2, to determine potential mechanisms through which these compounds influence the carcinogenic process. it could be observed that the inhibition of Caco-2 cell proliferation by isoflavones and saponins, suggesting a protective effect of these compounds in colon cancer. Using purified soy saponins, we found no negative effects on mouse growth, organ weights, or intestinal morphology when the diet contained up to 3% saponins by weight. Hence, soy isoflavones and saponins are likely to be protective of colon cancer and to be well tolerated. Continuing studies will explore the cancer-protective effects of these compounds in animal models (Ruth et al., 2012).

Ingesting oligosaccharides such as raffinose and stachyose, namely, encouraging igenous bifidobacteria in the colon against putrefactive bacteria.

The insoluble carbohydrates in soyprotien consist of the complex polysaccharides cellulose, hemicellulose, and pectin. The majority of soybean carbohydrates can be classed as belonging to dietary fiber.

Within soybean oil or the lipid portion of the seed is contained thephytosterols: Stigmasterol (17–21%), sitosterol(53–56%) and campesterol(20–23%) accounting for 2.5% of the lipid fraction.

Saponins, a class of natural surfactants (soaps), are sterols that are present naturally in a wide variety of food-plants: vegetables, legumes, and cereals–ranging from beans and spinach to tomatoes, potatoes and oats. Whole soybeans
contain from 0.17 to 6.16% saponins, 0.35 to 2.3% in defatted soy flour and 0.06 to 1.9% in tofu. Legumes such as soybean and chickpeas are the major source of saponins in the human diet. Sources of non-dietary saponins include alfalfa, sunflower, herbs and barbasco. Recent studies have shown that saponins are potential functional food ingredients because of their physiological properties.

Soy contains isoflavones like genistein and daidzein. It also contains glycine, an O-methylated isoflavone which accounts for 5–10% of the total isoflavones in soy food products. Glycine is a phytosteroid with weak estrogenic activity, comparable to that of the other soy isoflavones (Song et al., 1999).

Chickpea (Cicerarietinum L.) is an important pulse crop grown and consumed all over the world, especially in the Afro-Asian countries. It is a good source of carbohydrates and protein, and the protein quality is considered to be better than other pulses. Chickpea has significant amounts of all the essential amino acids except sulfur containing types, which can be complemented by adding cereals to daily diet. Starch is the major storage carbohydrate followed by dietary fiber, oligosaccharides and simple sugars like glucose and sucrose. Lipids are present in low amounts but chickpea is rich in nutritionally important unsaturated fatty acids like linoleic and oleic acid. β-sitosterol, campesterol and stigmasterol are important sterols present in chickpea oil. Calcium, magnesium, phosphorus and especially potassium are also present in chickpea seeds. Chickpea is a good source of important vitamins such as riboflavin, niacin, thiamin, folate and the vitamin A precursor, β-carotene. Like other pulses, chickpea seeds also contain anti-nutritional factors which can be reduced or eliminated by different cooking techniques. Chickpea has several potential health benefits and, in combination with other pulses and cereals, it could have beneficial effects on some of the important human diseases like cardiovascular disease, type 2 diabetes, digestive diseases and some cancers. Overall, chickpea is an important pulse crop with a diverse array of potential nutritional and health benefits (Jukanti, 2012).

Australian Sweet Lupins (Lupinusangustifolius) are high in protein, dietary fiber and antioxidants, very low in starch, and are gluten-free. Lupins can be used to make a variety of foods both sweet and savoury including everyday meals, traditional fermented foods, baked foods and sauces.

The lupin is devoid of starch, which is very unusual for a species of edible bean. Lupins have a thick seed coat (25%) which consists mainly of cellulose (insoluble fiber-bran) and its removal is the first step in lupin processing. The kernel (split) of lupin is rich in protein (40%), fiber (40%) and moderate in fat (8%) made up largely of unsaturated fatty acids. Intensive plant breeding programs have ensured that modern lupin varieties have relatively low levels of the alkaloids found in their ancestral genotypes. Lupins also contain moderate amounts of carotenoids; beta carotene, lutein, zeaxanthin and tocopherols (Vitamin E).
Australian sweet lupin features a higher calcium and phosphate content than cereals with trace element content varying in line with the mineral content of the soil in which the lupin is grown.

Lupin oils have high antioxidant capacities due in part to the presence of tocopherol (Vitamin E the total vitamin E content is about 2.3 - 4.6 mg/kg of oil (Gladstone et al., 1998).

Effect of seeds and probiotic on immunological its effect on increasing antioxidant enzymes could be indirect result of their effect on lipids metabolism. The histopathological results showed that rats supplemented with mixture of lupine, chickpea, soy protein and probiotic bacteria at 0.5 and 1% can prevent/reduce diet induce fatty liver. This fat reduction in the liver was confirmed by serum lipid analysis and by measurement of liver specific marker enzymes as mentioned before (Zafar and Mujahid; 1998 and Ahmed; et al.; 2003).

On the basis of the present results, it could be conclude that seeds mixture of lupine, chickpea, soy protein and probiotics especially at 1:1:1 and 0.5% may have synergistic effect and its intake of be useful for product high caloric food supplemented with probiotic bacteria (lactobacillus, bifidobacterium) accompanied by hyperlipidemia as it reduces feed intake and body weight, improves serum lipid profile, liver function and immunological activity in rats. Moreover, this mixture has a promising effect on the liver tissues as it ameliorates the histopathological lesions seen in this organ of rats.
